Introduction

Formula 1 is a motorsport sector characterized by the management and analysis of a huge amount of data (car telemetry, tyre condition, lap times, track temperature).

These data needs to be analyzed in order to fully understand the dynamics characterizing a specific Formula 1 Race.

Our goal is to develop a dashborad that can be used by a **race engineer** responsible for evaluating post-race data and comparing different strategies adopted by the teams.

Related Works

Author	Content	Our proposal
Lamprecht et al.	Interactive web-based tool providing a yearly calendar overview and detailed lap-time comparison	It guarantees a deeper tactical dive into a single race, integrating also a Strategy Gantt and a PCA view
Eckl et al.	Framework for analyzing F1 seasons with synchronized views, allowing for filtering by driver and season	Differently from Eckl's system, that is primarily descriptive, our proposal is white box and exploratory since it integrates real-time linear regression for tyre degradation triggered by user selection
Mugge and Zandieh	Exploration of importance of tyre management, performed using FastF1 and aiming to identify the optimal window lap life	While Mugge and Zandieh focuses on the predictive aspect, our tool focuses on the interpretative side.

Related Works

Author	Content	Our proposal
Msakamali	Investigation of the complexities of analyzing team-specific tactical implementations through telemetry and tyre performance case studies.	Differently from Msakamali's static analysis, our solution offers a highly coordinated environment, that allows for the analysis of technical elements that are treated separately in Msakamali's work
Sacha et al.	It faced the problem of visualizing the high-dimensional nature of a race stint	It follows the methodology suggested by Sacha's work, but using a dynamic PCA scatterplot that can be used as an entry point for exploration.

Dataset and Domain

The data we used comes from **Fast F1**, an open-source Python package that provides access to Formula 1 timing data and car telemetry.

We downloaded data related to **Monza 2024 Grand Prix**.

The dataset provides a lap-by-lap breakdown for each driver participating to the race.

The data dimensions are 4:

- Driver Information
- Performance Metrics
- Lap Context
- Track and Weather Conditions

Application Overview

Application Overview

Race Position Evolution:

Linechart representing the evolution of the driver's track position throughout the race

It adopts the following encoding:

- x-axis → lap number
- y-axis → race position

Drivers are identified through a continuous color scale where the two extremes are:

- red → for the driver in last position
- green → for the race winner

Application Overview

Lap Time Evolution:

Linechart representing the pacing of the drivers.

It adopts the following encoding:

- x-axis → lap number
- y-axis → registered lap time

Drivers are encoded as done in Race Position Evolution

A visualization of the linear regression of lap times within a stint allows to have a visual quantification of pace drop-off over time

Application Overview

Strategy Gantt:

It allows to illustrate the race strategies adopted by the grid.

The encoding is the following:

- x-axis → laps
- y-axis → drivers ordered by final race result
- horizontal bar → stint
- red reversed triangle → pit stop

The visual variables for the bars follows the Formula 1 domain convention, while the luminance of each bar encodes the progressive consumption of the tyre.

Application Overview

PCA Stint Analysis:

It is a scatterplot visualizing the results of PCA applied to stint features.

Each point represents a single stint and it is positioned according to the first two principal components.

Points are color-coded based on the tyre compound used.

Thanks to this representation the user can identify clusters or it can observe outliers.

Application Overview

Parallel Coordinates:

It allows to inspect the multivariate attributes of the stint

The encoding is the following:

- each polyline represents a single stint and it is color-coded according to the type of tyre used in that stint
- each vertical line represents a quantitative metric (Stint Length, Track Temperature, Sector Deltas, Speed Traps, Consistency Std).

Application Overview

Sidebar:

This component acts as control and summary panel.

It is divided into three sections:

- General Statistics → it contains aggregate context about the race
- Analytics (Details on Demand) → this section automatically generates comparative box plots based on user selections
- Legend → it describes the visual encoding adopted throughout the dashboard.

The One-Stop Strategy Efficiency

The race winner, Charles Leclerc, adopted a one pit stop strategy

Oscar Piastri adopted a two pit stop strategy and arrived second despite starting from pole position

Lap 1-15: Piastri is faster than Leclerc → Lap 15: Leclerc's pit stop → Lap 16: Piastri's pit stop

Lap 38: Piastri's pit stop due to augmenting lap times

← Lap 16-38: lap times of two drivers converge

After the pit stop Piastri was more faster than Leclerc, but he lost time during the pit stop and he was not able to reach the race winner before the end of the race

PCA Outlier Analysis

The PCA Stint Analysis allows to identify two technical anomalies:

- **Hulkenberg's Initial Stint** → in the PCA scatterplot most Medium tyre stint are clustered together, but this does not hold for Nico Hulkenberg's first stint.

This point is isolated due to a minimum stint length (only 5 laps) and inferior performances in S2 and S3, combined with the worst registered Speed FL value

- **Tsunoda's Technical Failure** → the dashboard clarified this anomaly because it is the only hard stint lasting only 7 laps. Tsunoda also registered the worst Sector 2 and 3 performances, despite decent Speed ST value, and this highlights his technical failure

Driver Ability in Tyre Management

Zhou and Ricciardo are isolated from all the other drivers who performed a one-pit stop strategy (Medium-Hard) and that used the hard compound for a high number of laps,

This is due to both drivers failing to reach the same speeds (SpeedST) as the leaders within the cluster

In addition, Zhou, compared to top-tier drivers, shows an inability to manage the hard compound.

**THANK YOU
FOR
THE ATTENTION!**
